ARTICLE

Survival of service firms in European emerging economies

Ichiro Iwasaki^a and Evžen Kočenda^b

^aInstitute of Economic Research, Hitotsubashi University, Tokyo, Japan; ^bInstitute of Economic Studies, Charles University, Prague, Czech Republic

ABSTRACT

Using a dataset of 126,591 service firms in 17 European emerging economies, this paper aims to estimate firm survivability in the years 2007–2015 and examine its determinants. We found that 31.3%, or 39,557 firms, failed during the observation period. At the same time, however, the failure risk greatly differed among regions, perhaps due to the remarkable gap in the progress of economic and political reforms. Moreover, the results of survival analysis revealed that large shareholding, labor productivity, and firm age played strong roles in preventing business failure beyond differences in regions and sectors.

KEYWORDS

European emerging economies; service industry; survival analysis; cox proportional hazards model

I. Introduction

Emerging economies in Central and Eastern Europe (CEE) and the former Soviet Union (FSU) were profoundly challenged by a wave of crises, starting from the global financial shock in 2008, followed by the EU sovereign debt crisis and the military conflict in Ukraine. By virtue of several attempts made in recent years, we are now revealing the magnitude of the European crises in these economies (Wise, Armijo, and Katada 2015; Brada and Wachtel 2016; Havlik and Iwasaki 2017). However, evidence regarding the service industry is scarce, although the sector has the largest employment in the region and, thus, is crucial for the stability of the national economy.

In this article, using a hand-crafted dataset of 126,591 non-financial service firms in 17 European emerging economies, we will first trace their survival during the period of 2007–2015 and, then, examine the determinants to survivability. For the latter aim, we will estimate a Cox proportional hazards model, paying a special attention to ownership structure, financial soundness, productivity, solvency, firm size, and age – variables that have been repeatedly verified as having roles preventing management failure in the literature (Manjón-Antolín and Arauzo-Carod 2008; Alfaro and Chen 2012; Varum and Rocha 2012; Dai et al. 2016; Basile, Pittiglio, and Reganatic 2017; Baek

and Neymotin 2018; Zhang, Zheng, and Ning 2018). In this survival analysis, we will also examine the possible impact of a country's progress in economic and political reforms, taking into account the fact that economic processes in emerging European economies were shown to be affected by those reforms as well as institutional changes (Roland 2000; Estrin et al. 2009; Hanousek, Kočenda, and Shamshur 2015). We expect the findings in this paper to contribute to the limited literature on the impact of European crisis shocks on emerging markets.

II. Data and methodology

We use data from Bureau van Dijk's Orbis database. Based on its 2006/07 and 2015/16 archives, we identified non-financial service companies that satisfied the following two conditions: first, they were actually operating at the end of 2006 in 17 European emerging economies; second, their survival status was traceable until the end of 2015. In this regard, we classify failed firms as those being liquidated, bankrupt, and/or dissolved. Companies in the category of mergers/acquisitions are not considered as failed based on the argument of Lanine and Vander Vennet (2007). Bailed-out firms were excluded from the sample. As a result, we confirmed that a total of 126,591 companies met the above

conditions. In addition to survival status, we also collected from the Orbis database a series of firmlevel covariates that enabled us to examine the determinants of survival for 84,772 of the above 126,591 firms in addition to two covariates related to progress in economic and political reforms provided by the European Bank for Reconstruction and Development (EBRD) and the Freedom House. The covariates used in our empirical analysis are exhibited in Table 1.

In the following sections, by estimating a nonparametric Kaplan-Meier cumulative hazard function and survival function referring to the survival status of 126,591 firms, we will first report the survivability of service firms in all 17 emerging economies in the period from 2007 to 2015 and those by country group (Central European country group - Czech Republic, Hungary, Poland, Slovakia; Eastern European country group - Bosnia, Bulgaria, Croatia, Macedonia, Montenegro, Romania, and Serbia; Baltic country group - Estonia, Latvia, and Lithuania; and FSU country group – Moldova, Russia, and Ukraine) and by sector according to the NACE Rev. 2 industrial classification.

Next, we will perform a survival analysis of a total of 84,772 service firms, employing a semiparametric Cox proportional hazards model, in which the effect of a covariate upon the hazard rate is supposed to be proportional throughout the observation period. In the Cox model, the form of the hazard function h(t) is assumed in the following way:

$$h(t|x_{i1},\cdots,x_{in})=h_0(t)\exp(\beta_1x_{i1}+\cdots+\beta_nx_{in}),$$

$$h_0(t)>0,$$

where $x_{i1}, x_{i2}, x_{i3}, \dots, x_{in}$ are covariates associated with the *i*th observation; and $\beta_1, \beta_2, \beta_3, \dots, \beta_n$ are their respective parameters to be estimated. In this model, the baseline hazard $h_0(t)$ depends only on time t, while covariates enter the model linearly. The above equation is estimated through the maximum likelihood method by taking the logarithms of both sides and transforming the equation into the following linear model:

$$\ln h(t|x_{i1},\dots,x_{in}) = \ln h_0(t) + \sum_{j=1}^n \beta_j x_{ij}.$$

To deal with right censoring, we adopt the Breslow approximation. Every parameter estimate β reported in this paper is a hazard ratio. The impact of endogeneity on our results is minimized, as our data and estimation approach satisfy restrictions specified by Liu (2012).

III. Estimation of firm survivability

Table 2 reports the survival status of 126,591 service firms in 17 European emerging economies in

Table 1. Definitions and descriptive statistics of covariates used in the empirical analysis.

Variable name	Definition ^a	Mean	S.D.	Median
Large shareholding	Dummy for firms with a dominant and block shareholder(s)	0.8207	0.3836	1
Foreign ownership	Dummy for ultimate ownership of foreign investors	0.0369	0.1886	0
ROA	Return on total assets (%) ^b	9.9162	20.4993	5.5500
Labor productivity	Natural logarithm of operating revenue per employee in Euros	-0.1337	1.6343	-0.1462
Solvency ratio	Solvency ratio (%) ^c	33.7765	34.3356	28.8000
Size	Natural logarithm of total number of employees	4.1920	0.9471	4.0073
Age	Years in operation since the company's establishment	9.6097	9.5192	8
Age ²	Squared value of the Age variable	182.9596	1502.6760	64
Enterprise reform	EBRD index of enterprise reform ^d	2.5204	0.5060	2.3000
Democracy	Freedom House index of democracy ^e	3.2502	0.7957	2.7500

Notes:

^bComputed using the following formula: (profit before tax/total assets) × 100

^cComputed using the following formula: (shareholder funds/total assets) × 100

dit is a five-grade index ranging from 1 to 4 + . A score of 1 denotes a marginal reform, while a score of 4+ denotes a high reform level similar to the standards and performance typical of advanced industrial economies.

^eComputed by 7 minus the value of the original index, which ranges from 1.00 (best) to 7.00 (worst)

Source: Covariates from large shareholding to Age² were extracted from the Bureau van Dijk (BvD) Orbis database (https://webhelp.bvdep.com). Covariates of enterprise reform and democracy were obtained from the website of the European Bank for Reconstruction and Development (EBRD) and the Freedom House (http://www.ebrd.com/home; https://freedomhouse.org/).

Notes:

Source: Authors' estimations

the period of 2007–2015. In this table, the exit rate denotes the ratio of companies that failed by the end of 2015 in all of the corresponding sample firms. This simple exit rate may not express the real risk of management failure when the data are censored. Hence, in addition to the exit rate, we also report a Nelson-Aalen estimate of cumulative hazard function that adapts to data subject to right censoring. From this table, we conjecture that the European crises dealt fatal damage to a large number of service companies in CEE and FSU countries. Actually, we found that 39,557, or 31.3% of 126,591 firms, failed during the observation period. The Nelson-Aalen estimate of cumulative hazard function for all 17 countries is 0.3650. The damage of the crises on the service industry in emerging economies was highly likely to be larger than that in developed economies.

At the same time, however, Table 2 also proves that there is a remarkable gap between country groups from this perspective: in fact, the exit rate (Nelson-Aalen cumulative hazard function) for Central European countries has a value of 0.1366 (0.1456), while that for FSU countries has a much larger value of 0.3713 (0.4484). In other words, service firms in FSU countries faced a risk of management failure almost 3 times greater than that of their counterparts in Central Europe. With

regard to companies in Eastern European and Baltic countries, they had almost the same level of failure risk (0.2353 (0.2634) versus 0.2337 (0.2599)), which is at an intermediate level between Central European and FSU countries. Panels (a) and (b) in Figure 1 display time series changes in firm survivability in all 17 emerging economies and by country group, respectively. The log-rank test for the equality of survivor functions for the four country groups strongly rejects the null hypothesis ($\chi^2 = 4131.51$, p = 0.000) and, hence, backs up the above findings. To sum up, the above results imply that transformation to a democratic and market-oriented system strongly affected the destiny of service firms in the former socialist emerging economies.

According to Table 2 and Panel (c) in Figure 1, there are certain differences in the survivability of service firms depending on the sectors they belong to: the exit rate (Nelson-Aalen cumulative hazard function) for the wholesale and retail trade sector shows the highest value of 0.3521 (0.4206) among 7 sectors, while the accommodation and food service sectors have the lowest failure risk of 0.2203 (0.2443). The risk of firm failure in the other 5 sectors ranges between 0.2468 (0.2784) and 0.3150 (0.3688). Overall, the failure risk in sectors that are closely related to international transactions and

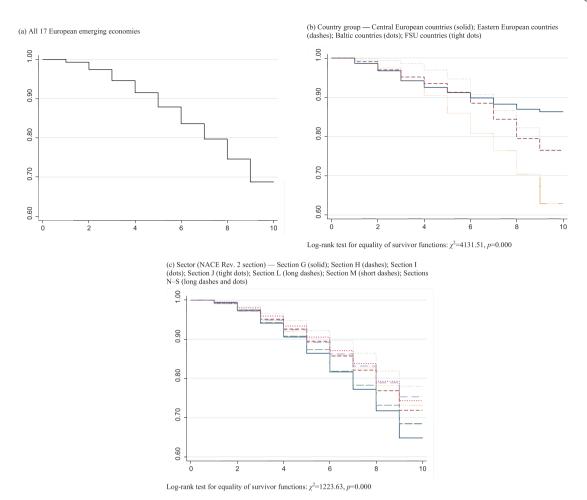

Figure 1. Kaplan-Meier survival function by country group and sector.

foreign direct investment tends to be higher than that in sectors inclined to the domestic market. The log-rank test for the 7 sectors rejects the null hypothesis ($\chi^2 = 1223.63$, p = 0.000), suggesting that the impact of European crises varied not only between country groups but also within the service industry. Therefore, in the next section, we report results based on the Cox model by country groups and sectors, in addition to aggregate estimates.

IV. Results of survival analysis

The overall picture is presented in Table 3, where in the first three columns (Models [1] to [3]) we report the aggregate results across all 17 countries and then contrast them with specific outcomes by country groups. Baseline model [1] is a standard specification where fixed effects account for country-specific unobserved factors. The other two models include a measure of the progress in

liberalization and institutional reform of the enterprise sector (Model [2]) and a measure of the level of democracy and political reforms achieved (Model [3]) shown to be linked with economic processes in emerging economies (Roland 2000; Estrin et al. 2009; Hanousek, Kočenda, and Shamshur 2015). Inclusion of the two measures is important for assessing whether and how progress in economic and political reforms in emerging European economies impacts firm survival. Further, in Table 4, we show results across NACE-defined sectors. On the whole, a high value of Harrell's C-statistic indicates sufficient explanatory power of the fitted models reported in these tables.

Ownership structure plays an important role with respect to the survival rate, in that large shareholding is the single most important exit-preventive factor (Table 3), with its impact well leveled across sectors (Table 4). Its impact is the strongest among firms from Eastern Europe, as

Table 3. Results of survival analysis for 17 European emerging economies and by country group.

Notes: This table contains results from the survival analysis using the Cox proportional hazards model. Table 1 provides detailed definitions and descriptive statistics of the covariates. Regression coefficients are hazard ratios. Standard errors are computed using the Huber-White sandwich estimator. z statistics are reported in parentheses beneath the regression coefficients. The Wald test examines the null hypothesis that all coefficients are zero. ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels, respectively.

the coefficient (0.1975) is way below the threshold of 1.0; in other groups, the effect is comparable. This finding underlines the significance of the extent of control that large shareholding represents: through management and the supervisory board, majority ownership facilitates more direct executive control of the company, which translates into its efficiency (Hanousek, Kočenda, and Shamshur 2015), especially in owner-controlled firms (Durand and Vargas 2003).

A complementary finding shows a similarly preventive role of foreign ownership, albeit with lower impact than the extent of control. However, country group results reveal that the position of foreign ownership pertains only to the FSU group; otherwise, coefficients are statistically insignificant. Similarly, foreign ownership improves the survival rate for firms operating in trade, transportation, and storage (Table 4, Models [1] and [2]); for other sectors, coefficients are statistically insignificant. Further, aggregate results indicate the importance of foreign ownership (Table 3, Model [1]). This finding is in line with the fact that, in emerging markets, foreign owners are documented to bring not only investments to firms, but also micro-level reforms, such as better management practices and improved corporate governance (Estrin et al. 2009). The impact of foreign ownership naturally declines somewhat when progress in economy-wide enterprise reforms or democratization is added to the estimated specification; at the same time, it is shown that the economic impact of those reforms on firm survival is substantial (Table 3, Models [2] and [3]).

Firm performance variables exhibit mostly economically insignificant effects (Table 3). Relative profitability, measured by ROA, has a neutral impact on firm survival, as the coefficients oscillate around 1.0 across all country groups (or sectors). Similarly, a firm's solvency shows a less-thannegligible exit-preventive effect. On the other hand, firms with higher labor productivity have better survival chances. While the effect is not dramatically large, it is far from being marginal and correlates well with the predictions of Melitz (2003) and the findings of Esteve-Pérez and Mañez-Castillejo (2008).The largest preventive impact can be found for firms operating in trade, transportation, and storage, plus

those engaged in scientific and technical activities (Table 4). This finding underscores the significance of productivity in service firms as an exitpreventive factor, since Duarte and Restuccia (2010) documented the increasing role of services in determining cross-country aggregate productivity outcomes.

Finally, the size of a firm on the aggregate level shows a marginally negative effect that is driven by the results of the FSU group, though. This result might reflect difficulties with management and the operation of larger units that historically dominated the FSU economic landscape (Havlik and Iwasaki 2017). On the other hand, larger firms in the Baltic and Eastern European groups have better or neutral survival chances, respectively; this finding reflects similar results in the literature (Varum and Rocha 2012). The age of a firm mildly improves its survival chances (Table 3), irrespective of the sector (Table 4). Age brings stability, but since the coefficients of its squared term equal one, it seems not to matter how old a firm gets.

As a robustness check, we estimated alternative parametric survival models and found that their estimates are quite similar to those of the Cox model (see Appendix).

V. Conclusions

Employing firm-level data from 17 European emerging economies, we found that 39,557, or 31.3% of 126,591 service firms, had a failure of management during the period of 2007-2015, suggesting a strong blow caused by recent financial and political crises in the CEE and FSU regions. However, the magnitude of the crises greatly differed among regions, perhaps due to the remarkable gap in the progress of economic political transformation (Åslund Djankov 2014; Gevorkyan 2018). Furthermore, the results of survival analysis revealed that, beyond the difference in regions and sectors, large shareholding, labor productivity, and firm age impacted firm survival substantially, which are in line with the empirical results in the previous studies cited in the Introduction. The findings in this paper provide specific insights into the consequences of the European crises in emerging economies.

Notes: This table contains results from the survival analysis using 6 parametric estimators for a robustness check. Table 1 provides detailed definitions and descriptive statistics of the independent variables. Models [1] to [3] report hazard ratios, while Models [4] to [6] report regression coefficients. Standard errors are computed using the Huber-White sandwich estimator. z statistics are reported in parentheses beneath the regression coefficients. The Wald test examines the null hypothesis that all coefficients are zero. ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels, respectively. Source: Authors' estimations
